

### S3: supporting information: catalog of sequence accession codes

The two tables in this supporting information section give the accession codes of all sequences used as inputs to the pan-filoviral design reported in this paper. The sets of all Ebolavirus and Marburgvirus protein and peptide sequences available through the U. S. National Center for Bioinformatics at the time of design were larger than the lists in the tables here because some sequences contained redundant information. As explained in the main body of the text, sequences that were either identical to another sequence, or are a shortened version of a longer sequence, were excluded. This allowed the elimination of all replicate information when necessary or desirable, and allowed the controlled duplication of sequences in a phylogenetically meaningful way when necessary to control for under-sampling of some viral species. Non-redundant sets of proteins (i. e. precisely the sets of proteins referred to in each column of the tables here) were used to calculate the coverage of peptide 9-, 10-, 11-, and 12-mers (i. e. potential epitopes) and to make the baseline simultaneously optimized mosaic cocktail designs discussed in the main text. Other designs that attempted to control for under-sampling of viral species duplicated sequences within poorly-sampled species.

The two proteins reported here, nucleoprotein (NP) and glycoprotein (GP) are listed in each table; “new” and “old” column headings refer to the inputs for the primary vaccine candidates (“new”) and the inputs used to design mosaics for testing the erosion of epitope coverage with time (“old”).
