Analysis of an ordered, comprehensive STM mutant library in infectious *Borrelia burgdorferi*: insights into the genes required for mouse infectivity

Tao Lin, Lihui Gao, Chuhua Zhang, Evelyn Odeh, Mary B. Jacobs, Loïc Coutte, George Chaconas, Mario T. Philipp, and Steven J. Norris

DIRECTORY	Pages
Table 1. Transposon insertions obtained in <i>B. burgdorferi</i> genes with predicted functions.	2-24
Table 2. Genes with a single insertion in the last 10% of the reading frame.	25-26
Table 3. Summary of mouse infectivity results obtained for STM clones with insertions in cp26.	27-28
Table 4. Oligonucleotides used in this study.	29
Figure 1. Construction of signature-tagged suicide himar1 transposon vectors pGKTSTM1-pGKTSTM11 for transposon mutagenesis of infectious <i>Borrelia burgdorferi</i> .	30
Figure 2. Distribution of transposon insertions in <i>B. burgdorferi</i> genes.	31
Figure 3. Transposon insertion sites for each of the plasmids present in <i>B. burgdorferi</i> B31 5A18NP1.	32-52
Figure 4. Distribution of individual MFI values obtained with high, intermediate, and low infectivity STM transposon mutant clones.	53
Figure 5. MFI values obtained by Luminex-based STM analysis are reproducible.	54
Figure 6. Sampling error may contribute to the variability of Luminex-based MFI values obtained in mouse infectivity analyses.	54
Figure 7. Heat map representations of the mouse infectivity of transposon mutants in the genes of <i>B. burgdorferi</i> plasmids.	55-60
Figure 8. Heat map representations of the mouse infectivity of transposon mutants in genes by functional group.	61-66
Spreadsheet S1. Transposon insertion sites in 4,479 clones derived by electroporation of <i>B. burgdorferi</i> 5A18NP1 with the <i>Himar1</i> suicide vector pGKT. (Excel format)	Separate Excel File
Spreadsheet S2. Mouse infectivity results obtained for 434 <i>B. burgdorferi</i> STM mutants, using Luminex STM analysis. (Excel format)	Separate Excel File

Table 1. Transposon insertions obtained in *B. burgdorferi* genes with predicted functions.^a Genes are arranged into broad (green) and narrow (blue) functional groups.

Predicted function	Replicon	Gene	Description	No. of genes	Gene(s) disrupted ^b	Disrupted only in last 10% of gene (insertion ratio)	Proportion of genes disrupted ^b
Amino acid biosynthesis				1	0	0	0.00
Serine family	Chr	BB601	serine OH methyltransferase (glyA)				
Biosynthesis of cofactors, prosthetic groups, and carriers				8	2	3	0.25
Folic acid				1	0	0	0.00

^a The Luminex FlexMAP™ microsphere specificity is indicated in parentheses. The forward slash represents the demarcation point between the Luminex FlexMap™ oligonucleotide-specific sequence and the STM tag-specific primer sequence.

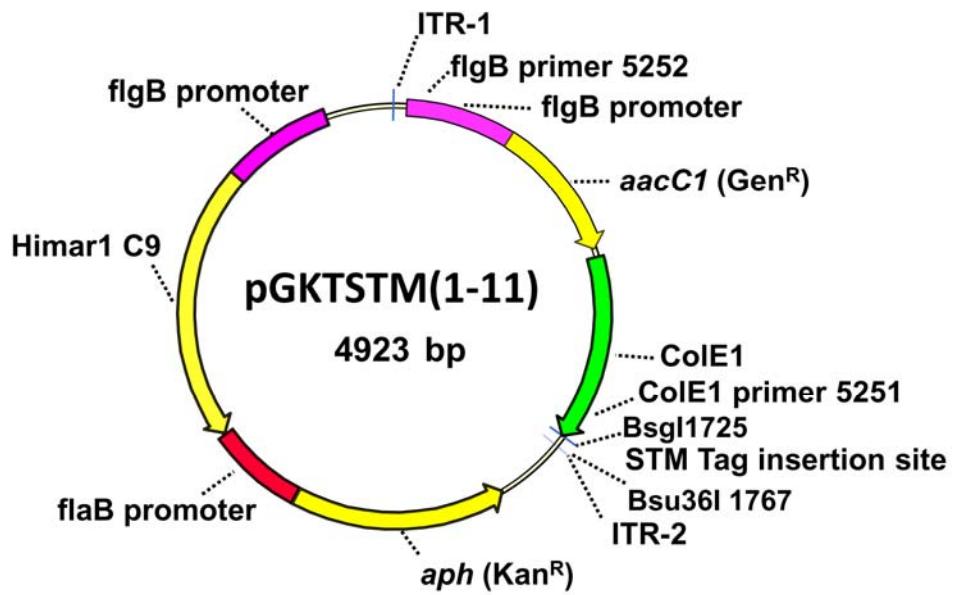

Fig. 1. Construction of signature-tagged suicide himar1 transposon vectors pGKTSTM1-pGKTSTM11 for transposon mutagenesis of infectious *Borrelia burgdorferi*. The signature-tagged suicide vectors pGKTSTM1-pGKTSTM11 vectors were constructed by inserting STM tags into a region between the CoIE1 origin and Inverted Terminal Repeat 2 (ITR2) in Himar1 transposon vector pGKT (2).

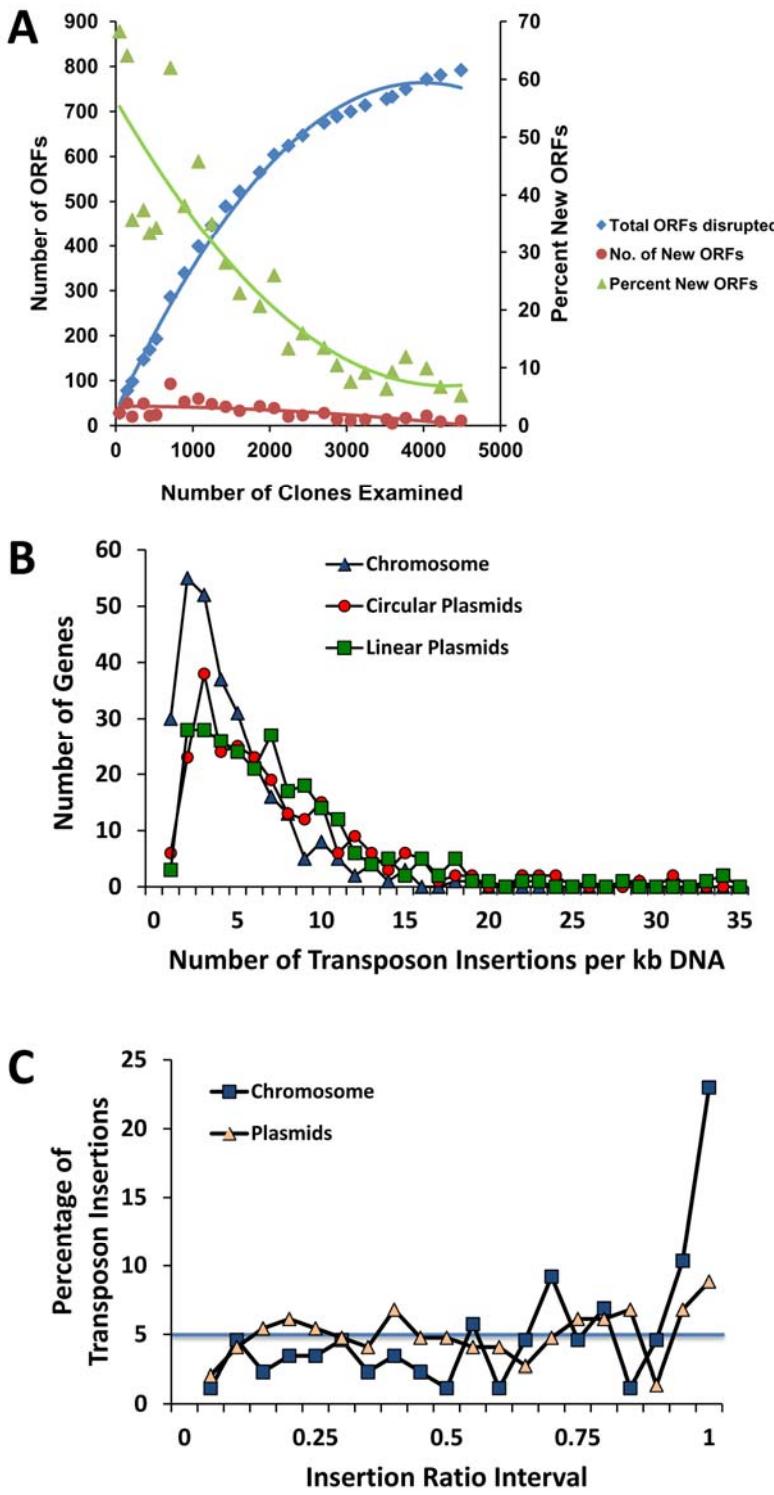

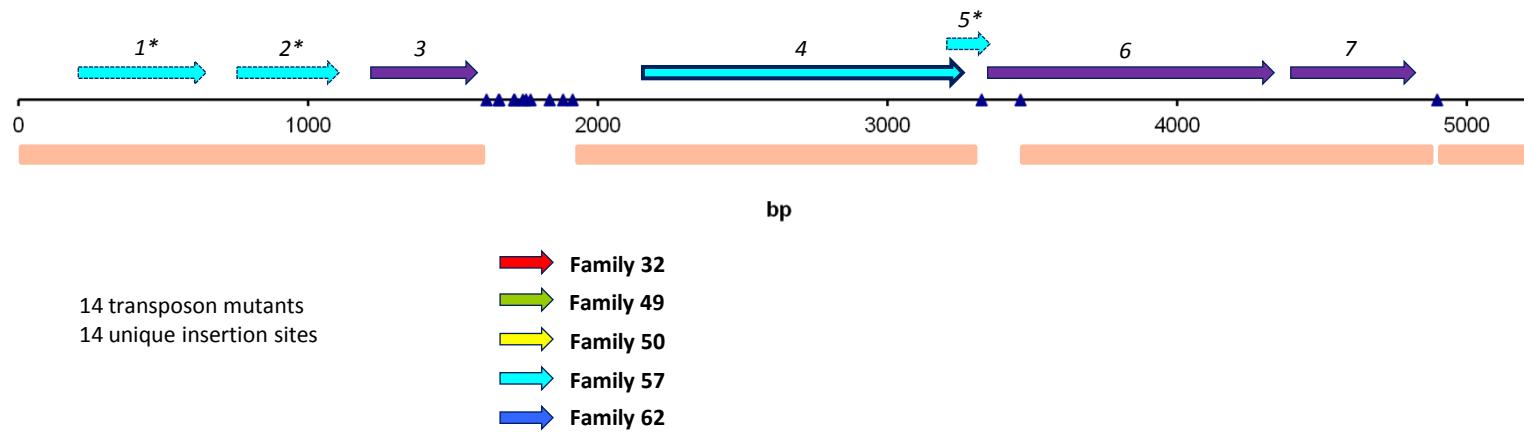

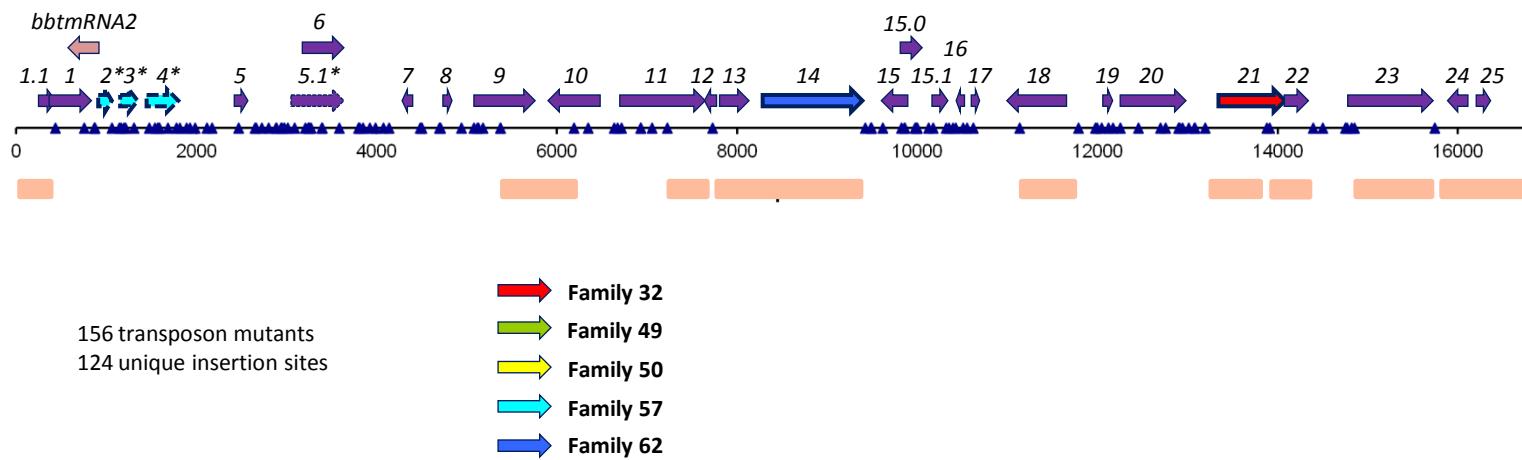

Fig. 2. Characteristics of transposon insertions in *B. burgdorferi* genes. (A) The number of genes with transposon insertions approaches saturation. Each data point represents a separate sequencing run for insertion site determination, which typically included 1-3 transformations. Total ORFs disrupted is the cumulative number of ORFs with insertions (final N = 790). Number of new ORFs is the number of ORFs in each sequencing run in which the ORF was not disrupted previously. Percent new ORFs represents the percentage of clones in a sequencing run that were in a newly disrupted ORF. Trendlines were generated in Microsoft Excel using the polynomial function. (B) Number of transposon insertions per kb DNA for genes in the chromosome, circular plasmids, and linear plasmids. Results for the 790 predicted genes with insertions are shown. (C) Preferential localization of transposon insertions in the last 10% of the open reading frame for the 233 genes that had only one insertion. Results are shown as the percentage of insertions in the insertion ratio intervals 0-0.05, 0.05-0.10, etc.

Fig. 3. Maps indicating the locations of STM transposon insertion sites in the plasmids of *B. burgdorferi* 5A18NP1. The genes are indicated as arrows; ORFs with dashed borders and an asterisk after the gene designation are pseudogenes. The key at the bottom of the figure indicates the color codes for four paralogous gene families (PFs) that have been postulated to be involved in plasmid replication or partitioning. The triangles on the line underlying the genes represent transposon insertion sites. Regions lacking transposon insertions (and thus containing genes potentially required for *B. burgdorferi* survival or plasmid retention) are marked as orange rectangles below the transposon insertion sites. The final panel is a histogram of the distribution of insertion sites at 500 bp intervals in the chromosome.

cp32-9 (Plasmid N) (30,651 bp)

Distribution of Transposon Insertion Sites - Chromosome

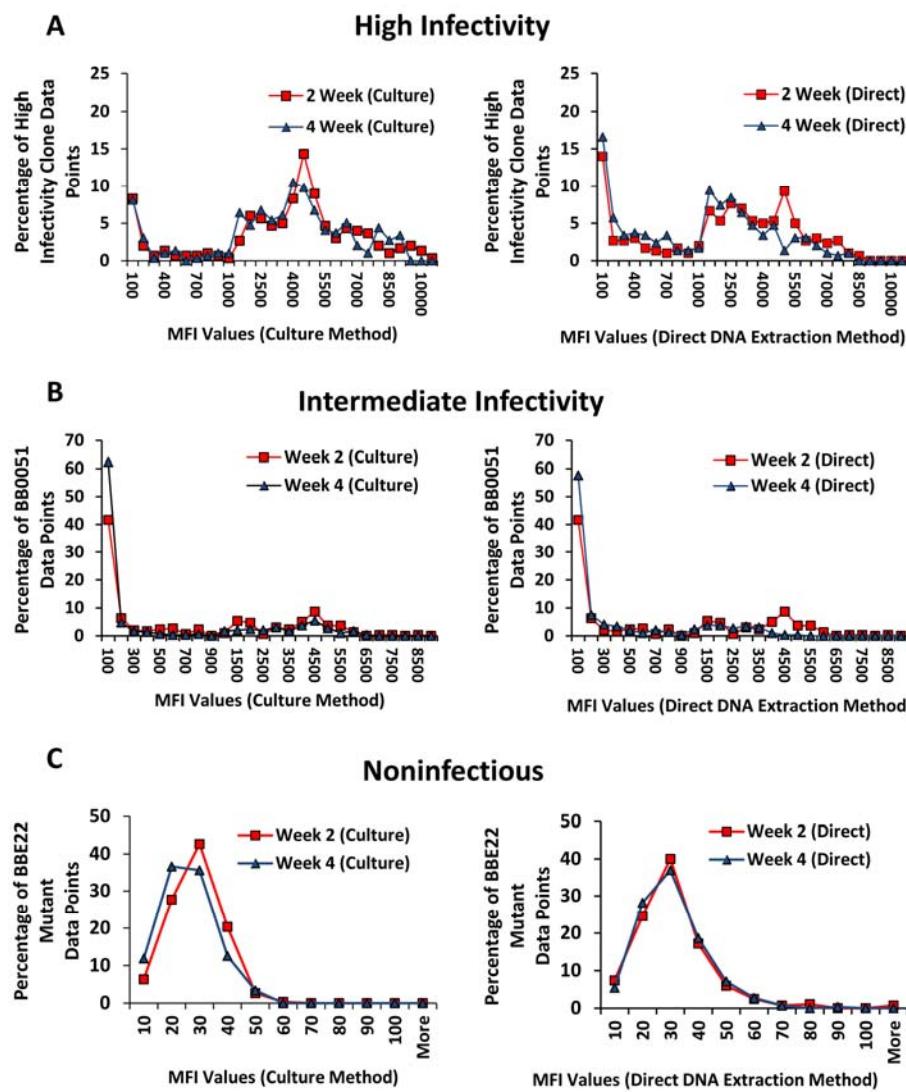

Fig. 4. Distribution of individual MFI values obtained with high, intermediate, and low infectivity STM transposon mutant clones. Results are shown for (a) the 20 clones that had the highest mean MFI values, (b) the intermediate infectivity BB0051 mutant T02P01A01, and (c) the low infectivity bbe02 (*pncA*) mutant T01P01A11. T01P01A11 and T02P01A01 are the negative and positive controls used in STM experiments. The data are subdivided into culture and direct DNA extraction methods, and into 2 week and 4 week samples. The minimum number of individual data points for each histogram is 286.

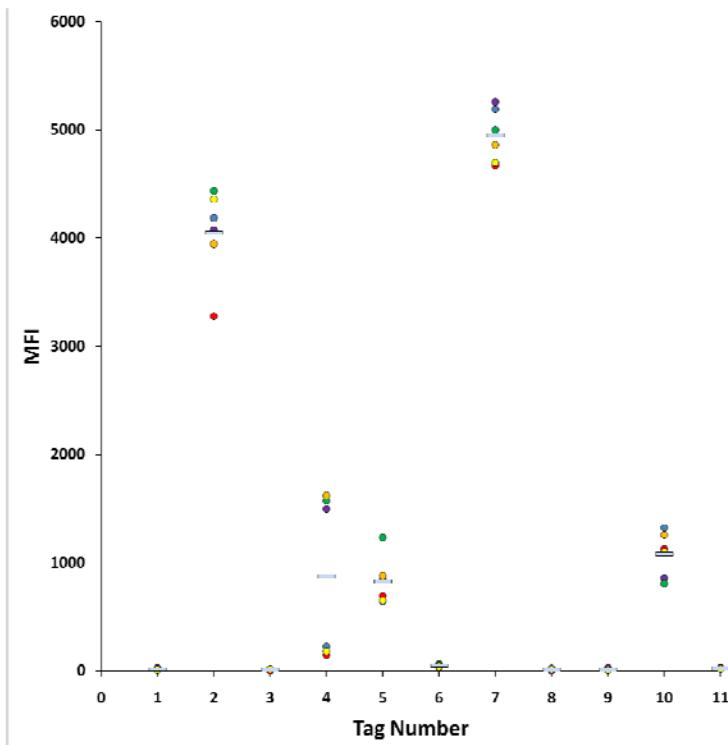

Fig. 5. MFI values obtained by Luminex-based STM analysis are reproducible. The results of six replicate determinations using Mouse 1 2 week direct tissue DNA extraction sample from Set 51 are shown. The X axis represents the 11 clones used to inoculate the animals. Consistent results were obtained in the 6 replicates.

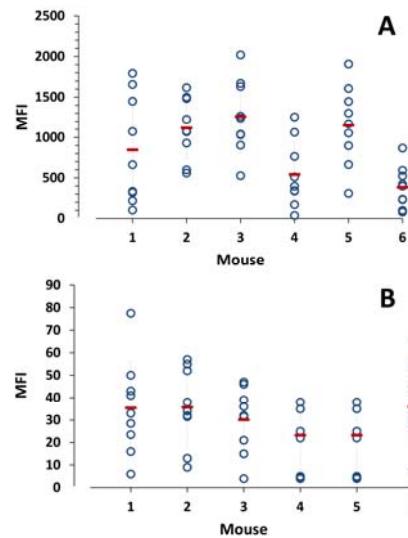

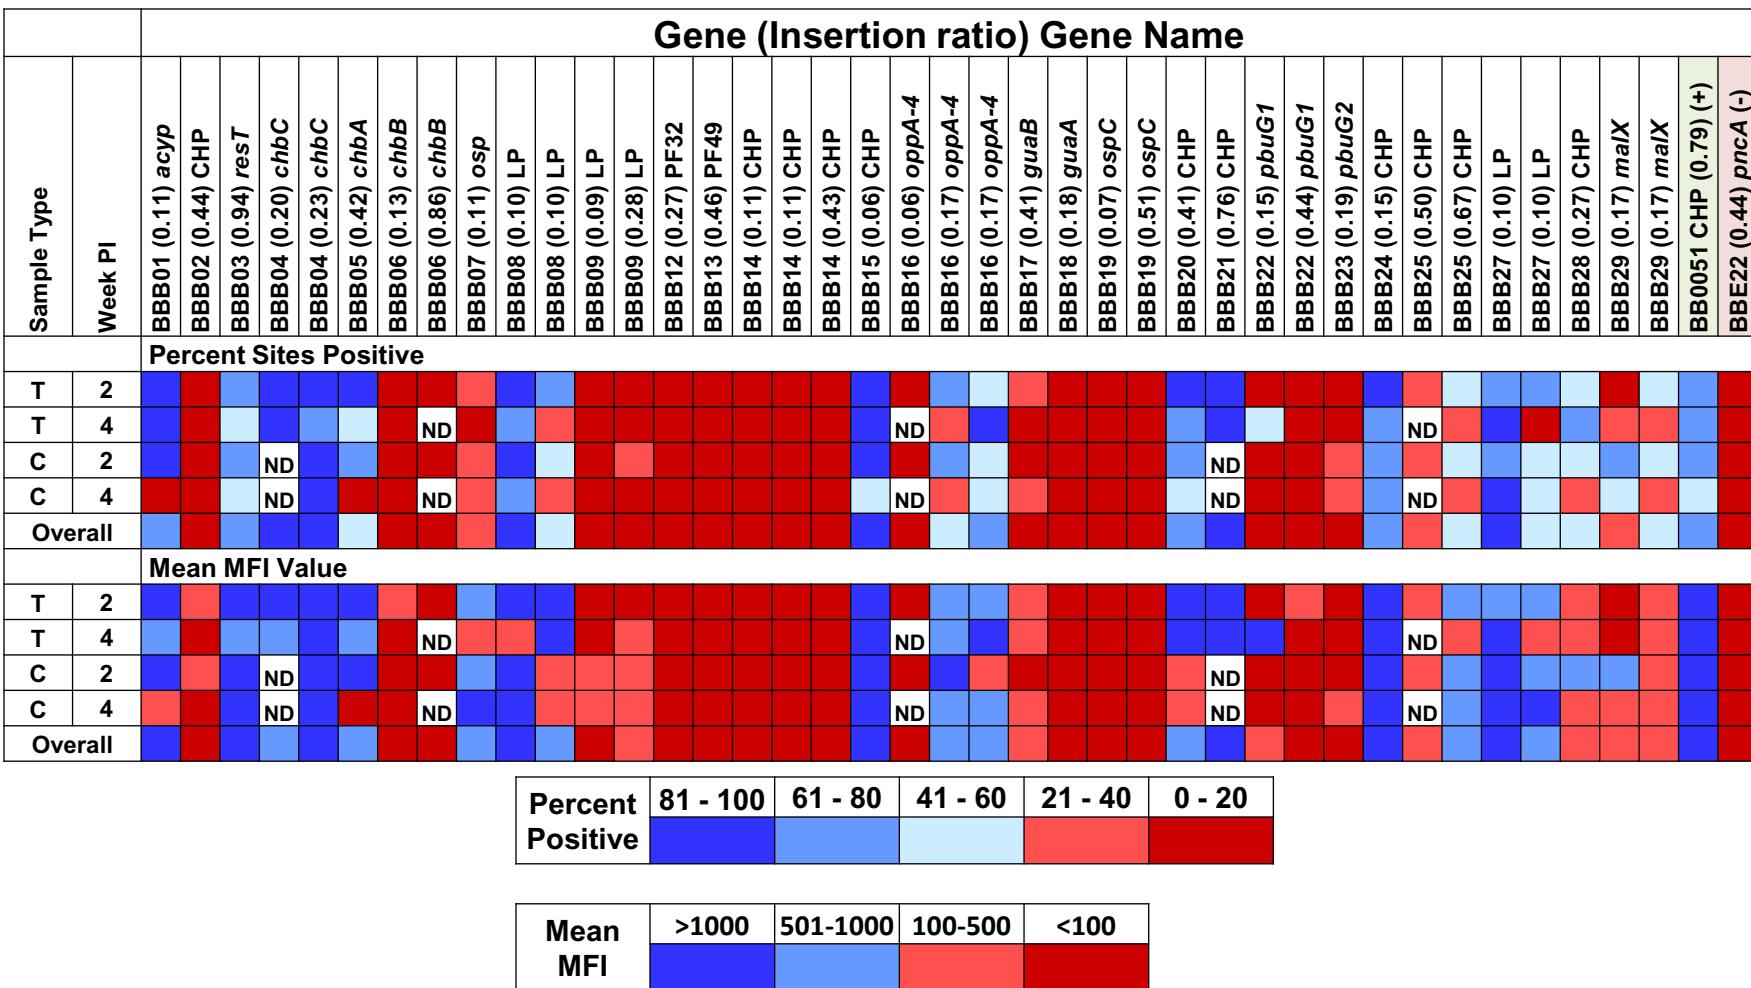

Fig. 6. Sampling error may contribute to the variability of Luminex-based MFI values obtained in mouse infectivity analyses. The STM Set 51 skin inoculation site tissue from 6 mice were used; mice 1-3 were infected for 2 weeks, whereas mice 4-6 were infected for 4 weeks prior to analysis. For each mouse, the skin inoculation site was subdivided into 9 equally-sized pieces, and each piece was processed separately by the direct DNA extraction method and evaluated for clone content by Luminex STM analysis. The results presented are for (a) the relatively high infectivity clone T07TC483 and (b) the low infectivity pncA mutant T01P01A01 (note difference in Y-axis scale). The MFI values obtained for each tissue specimen are shown; the red line indicates the mean value.

Figure 7. Heat map representations of the mouse infectivity of transposon mutants in the genes of *B. burgdorferi* plasmids. The plasmids shown are (A) cp26, (B) lp25, (C) lp28-1, (D) lp36, and (E) lp54. For each clone, results from Luminex STM analysis (see Fig. 4, Table S3) were grouped by week post inoculation (2 weeks or 4 weeks) and by DNA preparation method (Culture = use of organisms cultured from tissue; Tissue = use of DNA extracted directly from tissue). The data in each group were scored according to the percentage of samples with MFI values above the negative threshold (100) or to the mean MFI value; each result was then color coded as indicated in the key. Each colored box in the figure corresponds to 12 to 15 data points (typically 5 tissues from 3 mice). The composite results obtained in all experiments for the positive (*bb0051*) and negative (*pncA*) control mutants are provided at the right side of each figure. HP, hypothetical protein; CHP, conserved hypothetical protein; LP, lipoprotein; OMP, outer membrane protein; OSP, outer surface protein. Keys that indicate the clones and STM experiments utilized in each figure panel are provided at <http://www.uth.tmc.edu/pathology/borrelia/>.
